In this document we provide detailed results of Application 2: Preservation of human brain modules in chimpanzee brains. For this study we used the expression data originally collected in [1] and whose network analysis was published in [2]. The data consist of 18 human and 18 chimpanzee samples collected from 6 matching brain regions (3 samples per region in each species). The human brain modules were identified in [2], whereas the chimpanzee brain modules were identified in this work using the same module detection parameters that were used for the human modules.

In Figure 1 we show the contingency tables of human modules vs. chimpanzee modules. A complete table of calculated module preservation statistics can be found in the accompanying Supplementary Table S1. This is a flat comma separated value (CSV) text file that can be viewed in most standard spreadsheet software such as MS Excel and OpenOffice Calc. The columns indicate the reference set, test set, module, module size, observed preservation statistics, and their Z scores.

In Figures 2 and 3 we present the Z scores of quality statistics graphically, while in Figures 4 and 5 we present the Z scores of preservation statistics. In each figure, we plot the module quality and preservation Z scores (y -axis) as a function of module size (x -axis). The reference and test data sets are indicated in the title of each plot. Modules are labeled by their color and numeric labels (turquoise module also carries the numeric label 1, blue 2, brown 3, yellow 4, green 5, red 6, black 7). The dashed blue and green lines indicates the thresholds $Z = 2$ and $Z = 10$, respectively.

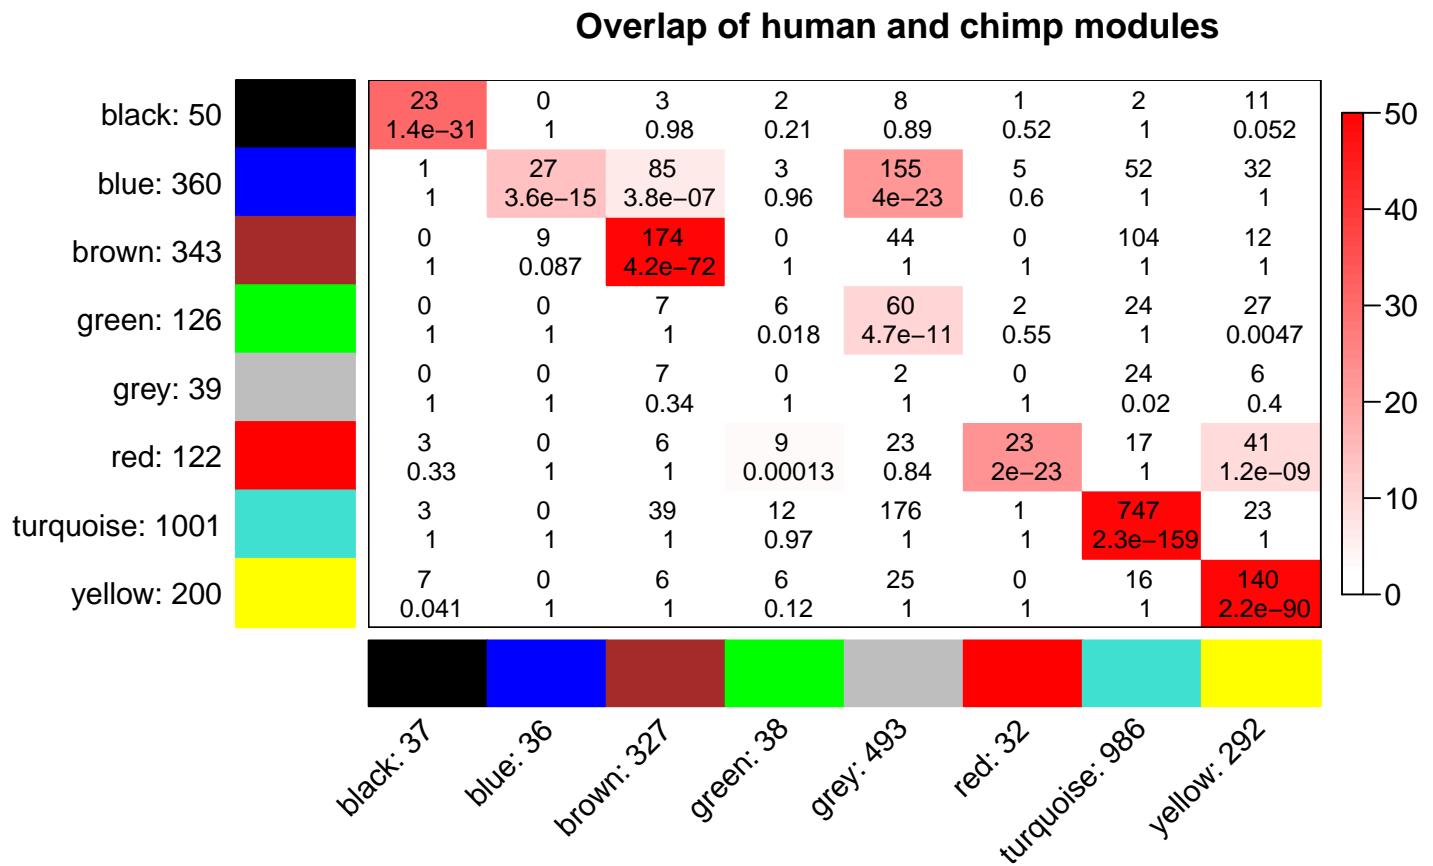

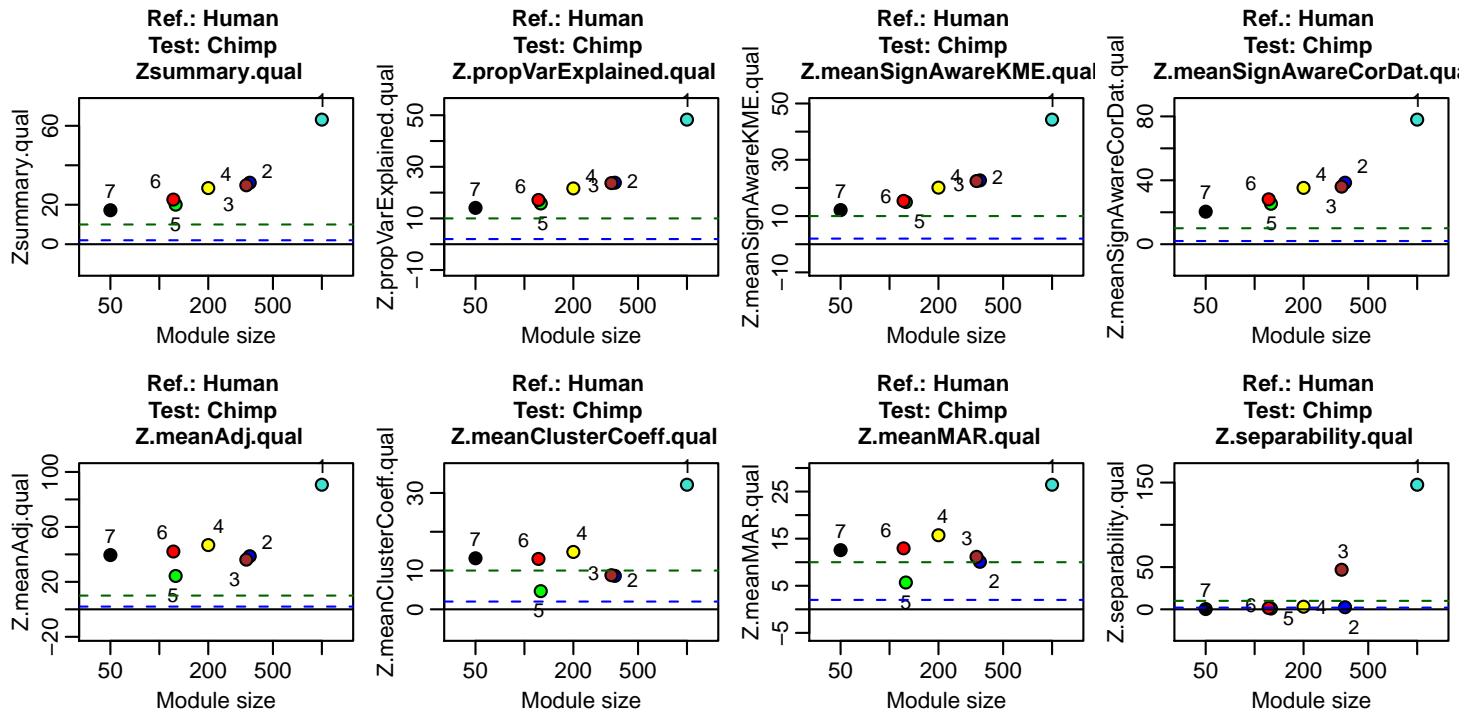

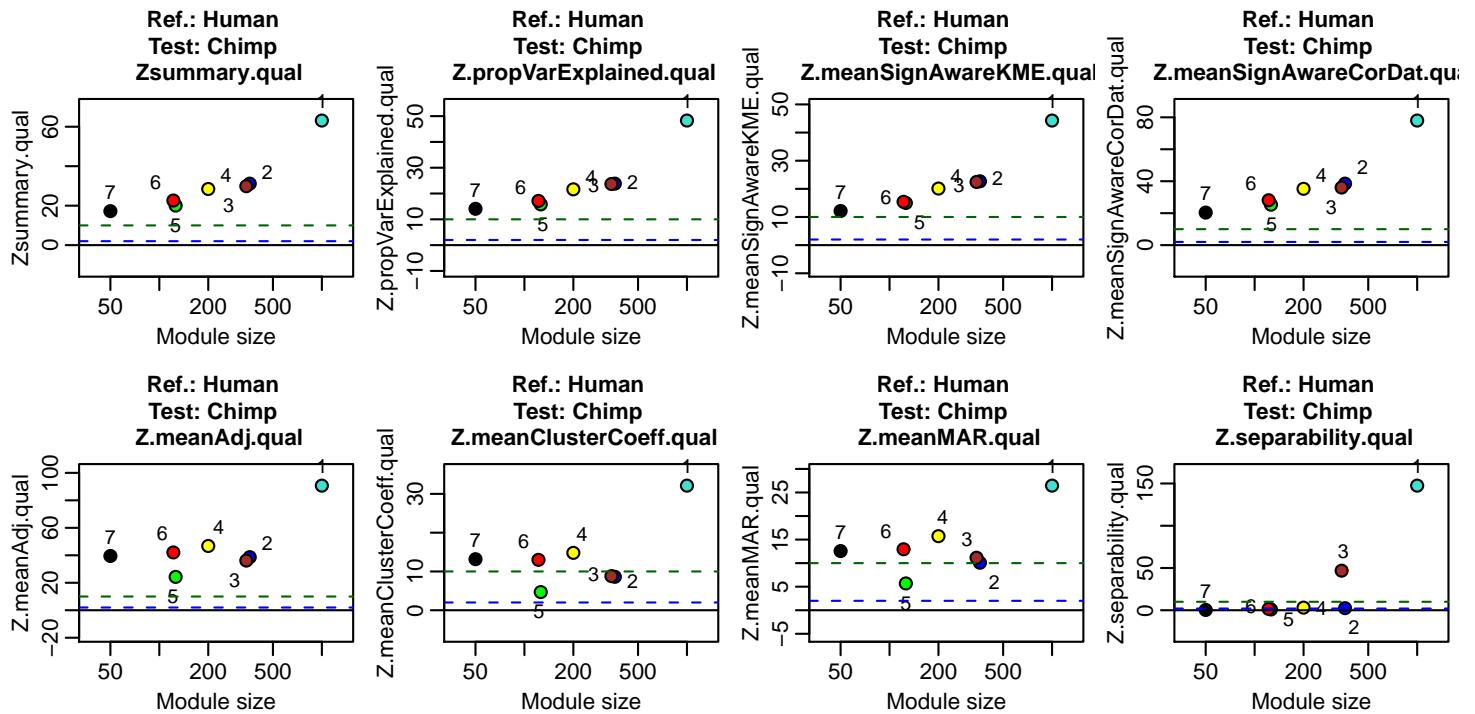

Figure 1. Overlap of human modules identified in [2] with chimpanzee modules identified using the same module detection settings. Each row corresponds to a human brain module, and each column corresponds to a chimpanzee brain module. Each module is labeled by its color label; we also indicate the total number of genes in the module. Within each cell, the top number indicates the number of genes in the overlap of the corresponding row and column modules, while the bottom number indicates the significance of the overlap, quantified by Fisher's exact test. The significance is also indicated by the color of each cell. Darker red indicates more significant overlap; the color legend is based on $-\log_{10}(p)$.
